1. Two linearly independent vectors  $\mathbf{w}_1, \mathbf{w}_2$  are a basis for a lattice  $\Lambda$  if  $\Lambda = \mathbb{Z}\mathbf{w}_1 + \mathbb{Z}\mathbf{w}_2$ . Show that the pair  $\mathbf{w}'_1, \mathbf{w}'_2$  are also a basis for  $\Lambda$  if, and only if,

$$\mathbf{w}_1' = a\mathbf{w}_1 + b\mathbf{w}_2$$
$$\mathbf{w}_2' = c\mathbf{w}_1 + d\mathbf{w}_2$$

for a matrix  $M = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$  with integer entries that has an inverse  $M^{-1}$  which also has integer entries. Prove that  $ad - bc = \pm 1$ .

- 2.  $\Lambda$  is a rank 2 lattice in  $\mathbb{R}^2$ . Choose a vector  $\boldsymbol{w}_1 \in \Lambda \setminus \{\boldsymbol{0}\}$  with norm  $||\boldsymbol{w}_1||$  as small as possible. Then choose  $\boldsymbol{w}_2 \in \Lambda \setminus \mathbb{Z}\boldsymbol{w}_1$  with norm as small as possible. Show that  $\Lambda = \mathbb{Z}\boldsymbol{w}_1 + \mathbb{Z}\boldsymbol{w}_2$ .
  - Let  $w_1$  be a fixed vector. Draw the region of possible values for  $w_2$ . Mark on your picture the points  $w_2$  that correspond to lattices  $\mathbb{Z}w_1 + \mathbb{Z}w_2$  that have a reflective symmetry.
- 3. Prove the formula for the chordal distance between two points  $z_1, z_2 \in \mathbb{C} \cup \{\infty\}$  algebraically by using the formula for stereographic projection.
- 4. Let  $\Gamma_1$ ,  $\Gamma_2$  be two disjoint circles on the Riemann sphere. Show that there is a Möbius transformation that maps them to two circles in  $\mathbb{C}$  centred on 0.
- 5. Find all of the Möbius transformations that commute with  $M_k$  for a fixed k. Hence describe the group

$$Z(T) = \{A \in \text{M\"ob} : A \circ T = T \circ A\}$$

for an arbitrary Möbius transformation T. Describe the set  $\{A(z_o): A \in Z(T)\}$  for  $z_o$  a point in  $\mathbb{P}$ .

- 6. Suppose that the Möbius transformation T is represented by the matrix M but that  $\det M \neq 1$ . Show that T is parabolic if and only if  $(\operatorname{tr} M)^2 = 4 \det M$ . Establish similar conditions for T to be elliptic, hyperbolic or loxodromic.
- 7. Prove that the composition of two inversions is a Möbius transformation. Show that every Möbius transformation can be written as the composition of inversions. How many inversions do we need?
- 8. Show that inversion in any circle is given by a map

$$J: z \mapsto \frac{a\overline{z} + b}{c\overline{z} + d}$$

for some complex numbers a, b, c, d with ad - bc = 1. For which choices of a, b, c, d is this map J an involution, that is  $J^2 = I$ ? Are these all inversions?

- 9. How many square roots of a Möbius transformation are there? This means, for each Möbius transformation T, how many Möbius transformations S are there with  $S^2 = T$ ?
- 10. Show that a Möbius transformation T represented by a matrix  $M = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$  is an isometry of the Riemann sphere for the chordal metric if, and only if,  $M \in SU(2)$ . Deduce that there is a group homomorphism  $\phi : SU(2) \to SO(3)$  with kernel  $\{I, -I\}$ . For each point  $z_o \in \mathbb{P}$ , show that there is a matrix  $M \in SU(2)$  with  $T(0) = z_o$ . Hence show that  $\phi$  is surjective and so  $SU(2)/\{I, -I\} \cong SO(3)$ .
- 11. Let p, q be two distinct points in  $\mathbb{P}$ . Show that there are infinitely many inversions that interchange p and q. Draw a picture illustrating the circles  $\Gamma$  for which inversion in  $\Gamma$  interchanges p and q. Now suppose that p' is another point of the Riemann sphere distinct from p and q. Mark on your picture all the possible values for J(p') for inversions J that interchange p and q.
  - Given 4 distinct points p, q, p', q', when can we find an inversion which interchanges both p & q and also p' & q'.
- 12. Show that there is an isometry T of  $\mathbb{D}$  with the hyperbolic metric that maps  $z_1$  and  $z_2$  to  $w_1$  and  $w_2$  respectively if, and only if,  $\rho(z_1, z_2) = \rho(w_1, w_2)$ .

13. Show that every straight line in the Euclidean plane can be written as

$$\ell = \{t\boldsymbol{u} + \boldsymbol{v} : t \in \mathbb{R}\}$$

for u a unit vector in  $\mathbb{R}^2$  and v orthogonal to u. Are u and v uniquely determined by the line  $\ell$ ? Deduce that the set of lines in the Euclidean plane corresponds to the points of a Möbius band. Is the same true for geodesics in the hyperbolic plane? (Hint: Consider the endpoints of the geodesic.) Is the same true for great circles in Riemann sphere?
